INTRODUCTION:
Maximizing production rates, reducing maintenance expense, and maintaining the safety of company employees are important priorities for the bulk material handling industry. Skirting is an important solution for reducing the dust from conveyor transfer points. Finding a skirting material that helps maintain production rates while lowering maintenance time and cost is also critical to a plant’s performance.

One solution to this problem is to change the skirting material on bulk material handling conveyors to an efficient, wear resistant, dust-reducing system. Changing out or adjusting skirting on conveyors is a costly job for many bulk material plants across the globe. Time required to change or adjust skirting can be extreme. Using a material that will last longer can reduce costly down time associated with changing or adjusting the skirting material for optimum performance.

With ever increasing production rates, there is a greater requirement for plants to run 24 hours a day, 7 days a week. In many cases, SBR rubber is not lasting between maintenance windows, resulting in spillage, airborne dust, premature failure of idlers, and belt damage, to name a few of the potential problems.

The misunderstanding within the industry in distinguishing the difference between new and traditional materials (polyurethanes and polyethylenes, ultra high molecular weight polyethylene (UHMWPE), natural rubber, etc.) to skirt transfer points prompted us to research the most economical and belt-friendly skirting material available. Ruling out materials that were hard and/or abrasive, we chose four materials to analyze:

- SBR Rubber 60 Duro Shore A (most commonly used)
- Natural Rubber 60 Duro Shore A
- Linatex Natural Rubber 60 Duro Shore A
- Argonics Polyurethane 69 Duro Shore A

**FRICTION**

The most important of the three tests is the skirting materials’ coefficient of friction value, due to its potential to transfer heat along skirted areas, causing premature belt damage. In this case, the lower the value \( \mu \), the better.

The polyurethane sample had the lowest friction value in all 4 tests.

The friction value of polyurethane is 64% lower than SBR rubber.

The 200 and 300 psi test data was not graphed, as the Linatex natural rubber samples peeled off twice due to excessive friction rates during testing.

Reducing friction between skirting and the conveyor belt surface is arguably the most important step in eliminating excessive skirting wear and belt damage. Conveyor belts are often replaced solely due to the skirting wearing a groove completely through the belt’s top cover, exposing the ply carcass, which results in tearing, spillage, belt tracking issues, etc.

Some rubber skirting is porous, which allows dust to adhere to the contact surface forming abrasive grit, which then wears a groove in the conveyor belt. Polyurethane, being inherently non porous, restricts the amount of dust being trapped under the skirt’s surface.

Rubber’s high friction = high abrasion and belt damage.

Polyurethane’s low friction and non porosity = less abrasion and belt damage.

**ABRASIVE RESISTANCE**

Test method: NBS abrasion (ASTM D1630), LANXESS laboratory test facility, USA

The graph to the left shows that Linatex natural rubber, whist achieving a high wear resistance, is not preferred as a conveyor skirting material due to its high friction coefficient. Linatex was not used in a case study for this reason.

The graph shows the polyurethane sample 326% more resistant to wear than SBR rubber.

This should not be confused with the true wear resistance of the materials tested due to the field situation allowing for friction of the belt and the skirting.

**TENSILE STRENGTH**

Test method: Extensometer (strain gauge)

The graph to the left shows polyurethane having the highest tensile strength.

A trial was conducted at the RG Tanna Coal Terminal to properly test the performance against the most commonly used skirting material, SBR rubber. The conveyor transfer point from the wharf conveyor to the ship loader was chosen as the test area.

Conveyor 6B-6BX transfer point specifications:
- 6000 tons per hour (TPH)
- 5.2 m/s (1023 fpm)
- 2400 mm rubber conveyor belt width (94.5 in.)

The polyurethane skirting was installed in Sept. 2008 and is still running as of June 2009.

Reported: 11 June 2009 only 1.5 mm wear present

CONCLUSIONS
High wear resistance, combined with a low coefficient of friction, is the ideal combination for a skirting material. Polyurethane produced the best results in the laboratory and field tests. Though the abrasion test results show polyurethane is 3-4 times more abrasion resistant than SBR rubber, once the friction factor was added in a real world scenario, we concluded that the polyurethane lasted 6-10 times longer than SBR rubber. This difference in wear rates is due to the polyurethane’s very low friction value. The abrasive resistance test ASTM D1630 simulates abrasion by means of grit and not the contact between the conveyor belts.

Further case studies have shown that as the belt speed increased, the wear rate of SBR rubber increased exponentially. However, polyurethane remained more constant due to the lower friction value.

The table below summarizes the suitability of each tested material.
ARGONICS provides the most reliable and cost-effective skirting available to meet the demands of your wear application.
